## **Posterior Pituitary Hormones**

Prof. Suheil Zmeili, MD; PhD School of Medicine Department of Pharmacology University of Jordan E-mail: szmeili@ju.edu.jo ADH (Vasopressin) & Oxytocin
 Nonapeptides (9 a.a)
 Known as neurohormones
 Synthesized in the hypothalamus
 Stored in the posterior pituitary → release
 ? Role as neurotransmitters (V<sub>1</sub>R's in CNS)
 Role of Oxytocin in man is unknown

## ADH (Vasopressin) (arginine vasopressin; argipressin)

## **Physiological and pharmacological actions:**

- Vasoconstriction &  $\uparrow$  platelet aggregation (V<sub>1</sub>a receptors)
- $\uparrow$  reabsorption of H<sub>2</sub>O from collecting ducts (V<sub>2</sub> receptors)
- † synthesis of certain clotting factors (VIII, Von Willebrand) (V<sub>2</sub> receptors)
- $\uparrow$  ACTH release (V<sub>1</sub>b receptors)
- Oxytocin-like activity

- Factors/Drugs ↑ ADH release:
- Hypovolemia, hyperosmolarity, pain, stress, nausea, fever, hypoxia
- Angiotensin II
- Certain prostaglandins
- Nicotine, cholinergic agonists, β-adrenergics
- Tricyclic antidepressants
- Insulin, morphine, vincristine...

# Factors/Drugs ↓ ADH release:

- Hypervolemia
- Hypoosmlarity
- Alcohol
- Atrial natriuretic peptide
- Phenytoin
- Cortisol
- Anticholinergics, *a*-adrenergics, GABA...

### Disorders affecting ADH release:

A. Excess production (inappropriate ADH secretion) → Dilutional hyponatremia

Causes:

- Head trauma, encephalitis
- Meningitis, oat cell carcinoma...

R<sub>x</sub>:

- Water restriction (R<sub>x</sub> of choice)
- Hypertonic saline solution
- Fludrocortisone  $\rightarrow \uparrow \mathbf{Na^+}$  blood level
- Loop diuretics (Furosemide)
- ? ADH antagonists

## ADH antagonists

- Conivaptan, a non-peptide V<sub>1</sub> & V<sub>2</sub> R antagonist given IV
- Tolvaptan; Lixivaptan & Satavaptan, a nonpeptide orally effective selective  $V_2R$ antagonists

## **Clinical uses:**

Inappropriate ADH secretion
CHF; liver cirrhosis...

B. Deficiency of ADH  $\rightarrow$  Diabetes insipidus (DI) $\rightarrow$  polyuria

- Causes:
- Idiopathic DI
- Congenital, Familial DI
- Hypothalamic surgery, head trauma, malignancies
- Gestational DI, overproduction or decreased clearance of vasopressinase

R<sub>x</sub>: ADH preparations (HRT)

## ADH preparations:

- Natural human ADH (Pitressin)
- Given I.M, S.C, has short half-life (15 min)
- Lypressin (synthetic, porcine source)
- Given intranasally, I.V, I.M, has short DOA (4hrs)
- Desmopressin (synthetic ADH-like drug=analogue)
   Given intranasally, S.C
- Most widely used preparation, has long DOA (12 hrs)

- Felypressin (synthetic ADH-like drug) Has strong vasoconstrictor activity Mainly used in dentistry
  Clinical uses to ADH:
  DI
  Nocturnal enuresis
- Hemophilia
- Bleeding esophageal varices

## Side effects to ADH preparations:

- Allergy
- Pallor
- Headache, nausea, abdominal pain in <sup>2</sup>'s (oxytocin-like activity)
- Anginal pain (coronary artery vasospasm)
- H<sub>2</sub>O intoxication (massive doses)
- Gangrene (rare particularly with desmopressin= has great affinity to  $V_2$  receptors)

# Drugs acting on the uterus

#### I. Uterine stimulants

### 1. Oxytocin: (nonapeptide=9 a.a peptide)

 Contracts the myoepithelial cells of the breast → milk letdown; milk ejection

Major stimuli, baby cry and suckling

- Contracts the uterus  $\rightarrow$  delivery

The uterus is insensitive to oxytocin in early pregnancy but its sensitivity increases with advanced pregnancy reaching maximum at time of delivery

- Has slight ADH-like activity

- Role in man ???

## Oxytocin MOA:

- Surface receptors → stimulation of voltagesensitive Ca<sup>++</sup> channels → depolarization of uterine muscles → contractions
- 1 intracellular Ca<sup>++</sup>

Clinical uses to oxytocin:

- Induction of labor

Drug of choice given in units in an I.V infusion

 Postpartum hemorrhage, I.M. Ergot alkaloids are better (ergonovine, methylergonovine, syntometrine= oxytocin+ergometrine)

- Breast engorgement, intranasally

 Abortifacient, I.V infusion. ≥ 20 weeks of gestation, ineffective in early pregnancy

Side effects to oxytocin: - Rupture of the uterus Major and most serious side effect - H<sub>2</sub>O intoxication and hypertension Due to its ADH-like activity Specific oxytocin antagonist Atosiban (inhibitor to uterine contraction=tocolytic), effective in the management of premature delivery, given IV. Has little vasopressin antagonistic effect

2. Prostaglandins: \* Dinoprostone (PGE<sub>2</sub>) Vaginal pessaries, inserts and gel, tab Abortifacient, induction of labor \* Dinoprost (PGF<sub>2 $\alpha$ </sub>) I.V infusion and intramniotic Same uses as dinoprostone

\* Carboprost (PGF<sub>2a</sub>) I.M and intramniotic Abortifacient and postpartum hemorrhage \* Gemeprost (PGE<sub>1</sub>) Vaginal pessaries Used to prime the cervix and helps to induce uterine contractions 3. Ergot alkaloids: Ergonovine, Methylergonovine I.M, oral

Ergot alkaloids remain the drugs of choice to manage postpartum hemorrhage

As compared to oxytocin, ergot alkaloids are more potent, they produce more prolonged and sustained contractions of the uterus and they are less toxic

Ergot alkaloids are contraindicated to be used as inducers to delivery (associated with high incidence of fetal distress and mortality)

# II. Uterine relaxants (Tocolytics) Major clinical use: premature delivery (weeks 20-36) $\rightarrow$ improve the survival of the newborn 1. β-adrenergic agonists: $\uparrow$ cAMP $\rightarrow \downarrow$ cytoplasmic Ca<sup>++</sup> \* Ritodrine I.V infusion Most widely used; highly effective \* Terbutaline, Oral, S.C, I.V

**Side Effects to β-adrenergics:** Sweating, tachycardia, chest pain... 2. Magnesium sulfate I.V infusion Activates adenylate cyclase and stimulates Ca<sup>++</sup> dependent ATPase Uses: premature delivery and convulsions of pre- eclampsia

3. Progesterone Oral, I.M Dydrogesterone 4. Oxytocin competitive antagonists Atosiban 5. Prostaglandin synthesis inhibitors Indomethacin, Meloxicam 6. Nifedipine **\*\*** Major contraindication to tocolytics: fetal distress
