

CHRONIC INTERSTITIAL (RESTRICTIVE, INFILTRATIVE) LUNG DISEASES, LEC 6

**MARAM ABDALJALEEL, MD.
DERMATOPATHOLOGIST AND NEUROPATHOLOGIST
UNIVERSITY OF JORDAN , SCHOOL OF MEDICINE**

SILICOSIS

- The most prevalent chronic occupational disease in the world
- Inhalation of crystalline silica mostly in **occupational** settings
- **quartz** is the most common

- Amorphous silica is less pathogenic
- **Workers in sandblasting and hard-rock mining are at high risk.**

PATHOGENESIS

- After **inhalation**, the particles **interact with epithelial cells and macrophages**.
- Activating the **inflammasome** and the release of **inflammatory mediators** by pulmonary macrophages
 - IL-1, TNF, fibronectin, lipid mediators, oxygen-derived free radicals, and fibrogenic cytokines.

- **When mixed with other minerals, the fibrogenic effect of quartz is reduced.**
- This fortuitous situation is commonplace, as **quartz** in the workplace is **rarely pure**.

MORPHOLOGY, SILICOTIC NODULES:

- **Macroscopically:**
 - early stages are tiny, barely palpable, discrete, pale-to-black (if coal dust is present) nodules
 - **Upper zones** of the lungs

Courtesy of Dr. John Godleski, Brigham and Women's Hospital, Boston, Massachusetts.

- **Microscopically:**
- **Silicotic nodules:**
 - **Concentrically arranged hyalinized collagen fibers surrounding amorphous center.**
 - With “**whorled**” collagen fibers
- **Polarized** microscopy reveals weakly birefringent silica

- Nodules may coalesce into **hard, collagenous scars**, with eventual **progression to PMF**
- **Fibrotic lesions** also may occur in **hilar lymph nodes and pleura.**

SILICOTIC NODULE

Concentrically arranged hyalinized collagen fibers surrounding amorphous center

SEVERAL COALESCENT COLLAGENOUS SILICOTIC NODULES

Courtesy of Dr. John Godleski, Brigham and Women's Hospital, Boston, Massachusetts.)

Silica crystals

CLINICAL FEATURES:

- **Asymptomatic:** detected as fine nodularity in the upper zones of the lung on routine chest radiographs
- after **PMF:** Shortness of breath, pulmonary hypertension and cor pulmonale
- **slowly progressive**, impairing pulmonary function to a degree that limits physical activity.

- **Increased susceptibility to tuberculosis**
- **lung cancer ?**

ASBESTOSIS AND ASBESTOS-RELATED DISEASES

<https://en.wikipedia.org/wiki/Asbestos>

ASBESTOS

- **Family of crystalline hydrated silicates with a fibrous geometry.**

ASSOCIATED WITH:

- (1) parenchymal interstitial fibrosis (asbestosis);
- (2) localized fibrous plaques or, rarely, diffuse pleural fibrosis.
- (3) pleural effusions
- (4) Lung carcinomas
- (5) malignant pleural and peritoneal mesotheliomas
- (6) laryngeal carcinoma

Pleural Plaques suggest asbestos exposure and do not cause symptoms

Malignant Pleural Mesothelioma:
Rare cancer of the lung lining

**ASBESTOSIS:
IS SCARRING OF THE LUNG CAUSED
BY ASBESTOS EXPOSURE**

PATHOGENESIS:

- once phagocytosed by macrophages → asbestos fibers activate the inflammasome and damage phagolysosomal membranes → release of proinflammatory factors and fibrogenic mediators →
 1. cellular and fibrotic lung reactions
 2. tumor initiator and a promoter
 - mediated by the oncogenic effects of reactive free radicals generated by asbestos fibers on the mesothelium.

- **Asbestos and tobacco:**

- The adsorption of carcinogens in tobacco smoke onto asbestos fibers results in remarkable **synergy** between tobacco smoking and the development of lung carcinoma in asbestos workers.

<https://health.clevelandclinic.org/even-smoking-just-one-or-two-cigarettes-a-day-increases-your-risk-of-lung-disease/>

MORPHOLOGY

diffuse pulmonary interstitial fibrosis

Asbestos body with beading and knobbed ends

fibrous pleural plaque

dense laminated layers of collagen (pink)

MORPHOLOGY

- **Diffuse pulmonary interstitial fibrosis** indistinguishable from UIP.
- **Asbestos bodies:**
 - golden brown, fusiform or beaded rods with a translucent center.
 - Formed of asbestos fibers coated with an iron-containing proteinaceous material
- Begins in the **lower lobes and subpleurally**

- **Pleural plaques:**
 - the most common manifestation of asbestos exposure
 - well-circumscribed plaques of dense collagen containing calcium
 - anterior and posterolateral aspects of the parietal pleura and over the domes of the diaphragm

CLINICAL FEATURES:

- Progressively worsening dyspnea **10 to 20 years after exposure.**
- cough and production of sputum.
- **static or progress** to congestive heart failure, cor pulmonale, and death.
- Pleural plaques are usually asymptomatic

OUTCOMES:

- The risk for developing **lung carcinoma** is increased **5-fold** for asbestos workers
- the relative risk for **mesothelioma** is more than **1000 times** greater than the risk for lung cancer
- Concomitant **cigarette smoking** increases the risk for lung carcinoma **but not for mesothelioma**.
- **Lung or pleural cancer** associated with asbestos exposure carries a particularly **poor prognosis**.

PULMONARY EOSINOPHILIA

PULMONARY EOSINOPHILIA

- number of disorders of immunologic origin, characterized by pulmonary infiltrates rich in eosinophils

DIVIDED INTO:

- **Acute eosinophilic pneumonia with respiratory failure**
- **Simple pulmonary eosinophilia (Loeffler syndrome)**
- **Tropical eosinophilia**
- **Secondary eosinophilia**
- **Idiopathic chronic eosinophilic pneumonia**

- **Acute eosinophilic pneumonia with respiratory failure:**
 - rapid onset of fever, dyspnea, hypoxia
 - respond to corticosteroids.

- **Simple pulmonary eosinophilia (Loeffler syndrome):**
 - transient pulmonary lesions
 - eosinophilia in the blood
 - benign clinical course

- **Tropical eosinophilia:**

- caused by infection with microfilariae and helminthic parasites

Figure 1: a) Microfilaria of *W. bancrofti* in a thick blood smear stained with Giemsa: b) Microfilaria of *B. malayi* in a thin blood

- **Secondary eosinophilia:**

- in association with asthma, drug allergies, and certain forms of vasculitis

- **Idiopathic chronic eosinophilic pneumonia:**

- disease of exclusion, once other causes of pulmonary eosinophilia have been ruled out.

SMOKING-RELATED INTERSTITIAL DISEASES

SMOKING-RELATED INTERSTITIAL DISEASES

- **Desquamative interstitial pneumonia (DIP)**
- **respiratory bronchiolitis**

DESQUAMATIVE INTERSTITIAL PNEUMONIA (DIP)

- The most striking histologic feature of DIP is the accumulation of large numbers of macrophages containing dusty-brown pigment (*smoker's macrophages*) in the air spaces
- Lymphocytes in alveolar septa
- +/- mild Interstitial fibrosis

accumulation of large numbers of macrophages within the alveolar spaces
only slight fibrous thickening of the alveolar walls.

Outcome:

- good prognosis
- excellent response to steroids and smoking cessation, however, some patients progress despite therapy.

RESPIRATORY BRONCHIOLITIS

- common lesion in smokers
- presence of pigmented intraluminal macrophages akin to those in DIP, **but** in a “bronchiolocentric” distribution (first- and second-order respiratory bronchioles).
- Mild peribronchiolar fibrosis.
- As with DIP, presents with gradual onset of dyspnea and dry cough
- symptoms recede with smoking cessation.

A 60 year old gentleman had progressively worsening dyspnea over the past 12 years. He has noticed a 7-kg weight loss in the past 2 years. He has a chronic cough with minimal sputum production and no chest pain. On physical examination, he is afebrile and normotensive. A chest radiograph shows extensive interstitial disease. Pulmonary function tests show diminished lung volumes and capacities. Increased exposure to which of the following pollutants is most likely to produce these findings?

A Carbon monoxide

B Silica

C Tobacco smoke

D Wood dust

ANOTHER CASE?!

A 42 year old lady had a low-grade fever and worsening non productive cough and dyspnea for the past 2 years. On examination, she has breath sounds in all lung fields. A chest CT scan shows reticulonodular pattern of infiltrate. An arterial blood gas show mild hypoxemia and normal CO₂. Pulmonary function tests show decreased lung capacities and volumes. Her pulmonary compliance is reduced. What is the most likely diagnosis?

- A α 1-Antitrypsin deficiency
- B Diffuse alveolar damage
- C Nonatopic asthma
- D Sarcoidosis
